ABSTRACT

One of the essential pieces of hardware in most digital signal processing (DSP) systems is the multiplier. Digital communications, spectrum analysis, and digital filtering are examples of common DSP applications where multipliers are crucial. Power dissipation becomes one of the main design restrictions due to the fact that many modern DSP applications are aimed at portable, battery-operated systems. Reducing a multiplier's delay is crucial to achieving the design's goals since multipliers are fairly complicated circuits that often run at a high system clock rate. This study proposes a high speed multiplier that is effective in terms of speed, using half adders for partial product addition and Urdhva Tiryagbhyam[1], a sutra from Vedic mathematics, for multiplication. The code is written in VHDL and results shows that multiplier implemented using Vedic multiplication is efficient in terms of area and speed compared to its implementation using Array and Booth multiplier architectures. The hardware requirement is large thus increasing the time delay. The basic building blocks should be reduced to achieve less time delay. The work can be extended tothe adders used can be re modified using basic gates and multiplexer.

INTRODUCTION

In arithmetic operations, multiplication is a crucial fundamental process. In many Digital Signal Processing (DSP) applications, including convolution, Fast Fourier Transform (FFT), filtering, and in microprocessors in their arithmetic and logic unit, computation-based operations based on multiplication, such as multiply and Accumulate (MAC) and inner product, are currently implemented. Many algorithms, including the array, Booth, and modified Booth algorithms, can be used to implement multiplication. The well-known array multiplier has a predictable structure. The add-and-shift method is the basis of the multiplier circuit. The multiplicand is multiplied by one multiplier bit to produce each partial product. The partial product are shifted according to their bit orders and then added. Booth Multipliers is a powerful algorithm for signed-number multiplication, which treats both positive and negative numbers uniformly. This method that will reduce the number of multiplicand multiples. For a given range of numbers to be represented, a higher representation radix leads to fewer digits. The partial-sumadders can also be rearranged in a tree like fashion, reducing both the critical path and the number of adder cells needed. The presented structure is called the Wallace tree multiplier The tree multiplier realizes substantial hardware savings for larger multipliers. The propagation delay is reduced as well. In fact, it can be shown that the propagation delay through the tree is equal to O (log3/2 (N)). While substantially faster than the carry-save structure for large multiplier word lengths, the Wallace multiplier has the disadvantage of being vary irregular, which complicates the task of an efficient layout design.

LITERATURE SURVEY

Rapidly growing technology has raised demands for fast and efficient real time digital signal processing applications. Multiplication is one of the primary arithmetic operations every application demands. A large number of multiplier designs have been developed to enhance their speed. Active research over decades has lead to the emergence of Vedic Multipliers as one of the fastest and low power multiplier over traditional array and booth multipliers.Honey Durga Tiwari.et.al talked about designing a multiplier and square architecture is basedon algorithm of ancient Indian Vedic Mathematics, for low power and high speed applications. They explained Urdhvatiryakbhyam and Nikhilam algorithm and found that Urdhvatiryakbhyam, is applicable to all cases of multiplication but due to its structure, it suffers from a high

carry propagation delay in case of multiplication of large numbers. This problem has been solved by introducing Nikhilam Sutra which reduces the multiplication of two large numbers to the multiplication of two small numbers. Prof J M Rudagil.et.alldesigned a multiplier using vedic mathematics. They explained Urdhvatiryakbhyam and found that it is efficient Vedic multiplier with high speed, low powerand consuming little bit wide area was designed. It was also found that the multiplier basedon vedic sutras had execution delay of almost half of that of binary multiplier. Sree Nivas A .et.all presented a technique that modifies the architecture of the Vedic multiplier by using some existing methods in order to reduce power. They explained Nikhilam sutra and double base number system. Nikhilam sutra method is not valid for negative numbers. They found that Vedic Multiplier without any Modification has high power consumption. Vedic Multiplier with modified Two's complement block has less power consumption with cost of delay and area. Full adders are designed for a 16-bit vedic multiplier to decrease number of slices and delay. The results obtained are compared and it is found that the reformed full adders have less delay. The design is implemented using four adders of different techniques such as full adder using two half adders and an OR gate. Second modified full adder is designed by using XOR gate and 2:1 multiplexer, third modified full adder by using two 4:1 multiplexer and fourth modified full adder using a combination of XOR gate, XNOR gateand a 2:1 multiplexer. After comparing the results, they concluded that the third modified full adder has better performance [3]. Gate diffusion input (GDI) is a method used for describing the structure of low-power digital combinatorial circuit. Consumption of power, delay that is produced and complexity of the circuit are reduced using this technique; thereby it maintains less complexity in logical layout. The GDI technique is implemented using two transistors for a deep range of complex logic design [4]. A high speed 32-bit vedic multiplier is designed. For addition of partial products in a 32-bit vedic multiplier Kogge stone adder and a ripple carry adder is used. Two multipliers are implemented using these two methods and results are compared with these two multipliers [5]. In 8-bit multiplier which is implemented using Urdhva Tiryagbhyam sutra, the partial product addition is realized using carry skip technique. A digital processor requires a multiplier as it is a basic block in the processor [6]. A 32-bit vedic multiplier is proposed using one carry save adder. The input of multiplier is arranged intwo 16-bit numbers to apply it stepwise using Urdhva Tiryagbhyam sutra and the partial product is added using one carry save adder thus reducing the hardware blocks in the circuit [7]. The processors are integrated into one chip as demand of complex processors is increased. But the load on the processor is not reduced. To reduce this load, the main processor is equipped with co-processors [8]. Design of a hybrid FIR filters using vedic multipliers and fast adders is todays need in many DSP processors. FIR filters play a significant role in the field of digital signal processors to eliminate noise suppression in electro cardio graph, imaging devices and the signal stored in analog media. So filter evaluation is accomplished to reduce the noise level. Multipliers and adders play a vital rolein determining the performance of FIR filter. They have proposed modified Annuprya vedic multiplier methods with Kogge Stone fast adder for implementation in the direct form FIR filter [9]. Multipliers play a major role in today's digital signal processing and various other applications. Both signed and unsigned multiplications are required in many computingapplications.

PROPOSED SYSTEM

Vedic mathematics - a gift given to this world by the ancient sages of India.A system whichis far simpler and more enjoyable than modern mathematics. The word "Vedic" is derived from the word "Veda" which means the store-house of all knowledge[1].Vedic math was rediscovered from the ancient Indian scriptures between 1911 and 1918 by Sri Bharati Krishna Tirthaji (1884-1960), a scholar of sanskrit, Mathematics, History and Philosophy.It ispart of four Vedas (books of wisdom). It is part of Sthapatya- Veda (book on civil engineering and architecture), which is an upaveda (supplement) of AtharvaVeda[2]. Vedic mathematics is mainly based on 16 Sutras dealing with various branches of mathematics like arithmetic, algebra, geometry etc. These Sutras along with their brief meanings are enlisted below alphabetically[3].

1. (Anurupye) Shunyamanyat - If one is in ratio. The other is zero.
2. Chalana-Kalanabyham Differences and Similarities.
3. EkadhikinaPurvena - By one more than the previous one.

4. EkanyunenaPurvena - By one less than the previous one.
5. Gunakasamuchyah - The factors of the sum is equal to the sum of the factors.
6. Gunitasamuchyah - The product of the sum is equal to the sum of the product.
7. NikhilamNavatashcaramamDashatah - All from 9 and the last from 10.
8. ParaavartyaYojayet - Transpose and adjust.
9. Puranapuranabyham - By the completion or non completion.
10. Sankalana-vyavakalanabhyam - By addition and by subtraction.
11. ShesanyankenaCharamena - The remainders by the last digit.
12. ShunyamSaamyasamuccaye - When the sum is the same that sum is zero.
13. Sopaantyadvayamantyam - The ultimate and twice the penultimate.
14. Urdhva-tiryakbhyam - Vertically and crosswise.
15. Vyashtisamanstih - Part and Whole.
16. Yaavadunam - Whatever the extent of its deficiency

Proposed multiplier architecture of 64x64 bit vedic multiplier and major change adopted here is use of half adder for addition of partial products.

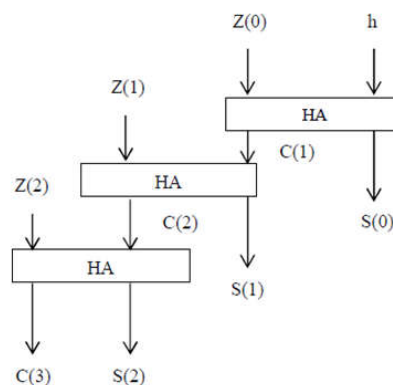

Figure 1: Addition of partial products with previous carry

The ancient vedic mathematics consists of a set of 16 sutras or main formulas and their 13 corollaries which can be efficiently used to solve mathematical calculations. One of the sutra is Urdhva Tiryagbhyam which means vertically and crosswise. This sutra can be used to perform a multiplication. The process of multiplication by using Urdhva Tiryagbhyam sutra is as follows, First step is to multiply the first digit that is left hand most digit of multiplicand with first digit of multiplier. The product is written as first digit in the answer. In second step multiply second digit of multiplicand with first digit of the multiplier and first digit of the multiplicand with second digit of multiplier, add the product. The result is written as second digit in the answer. Third step is to multiply second digit of multiplicand with second digit of multiplier, write the product as third digit in the answer.

SIMULATION RESULTS AND DISCUSSION

Timing Summery

```
Timing Summary:
---------------
Speed Grade: -12

   Minimum period: No path found
   Minimum input arrival time before clock: No path found
   Maximum output required time after clock: No path found
   Maximum combinational path delay: 29.967ns

Timing Detail:
--------------
All values displayed in nanoseconds (ns)

================================================================================
Timing constraint: Default path analysis
  Total number of paths / destination ports: 532354 / 128
--------------------------------------------------------------------------------
Delay:                29.967ns (Levels of Logic = 47)
  Source:             x<4> (PAD)
  Destination:        z1<128> (PAD)

    ----------------------------------------------
    Total                     29.967ns (10.624ns logic, 19.343ns route)
                                       (35.5% logic, 64.5% route)

CONCLUSION

A 64-bit vedic multiplier is designed by using Urdhva Tiryagbhyam Sutra of ancient vedic mathematics using VHDL and simulated on Xilinx ISE 14.7. The performance parameters like number of slice LUTs, number of bounded IOBs and combinational delay are analyzed and it is found that the number of slice LUTs used are 1758 out of 27288, number of bounded IOBs used are 128 and combinational delay is 54.037ns. The multiplier is designed using four 16-bit multiplier, one 32-bit full adder and two 48-bit full adders. The hardware requirement is large thus increasing the time delay. The basic building blocks should be reduced to achieve less time delay. The work can be extended to the adders used can be remodified using basic gates and multiplexer. The code is written in VHDL and results shows that multiplier implemented using Vedic multiplication is efficient in terms of area and speed compared to its implementation using Array and Booth multiplier architectures.
